# TV-Stereo-Sound

TDA 6612

Preliminary Data

Bipolar IC

Features

The TDA 6612 represents a complete TV stereo system controlled by the I²C bus according to German TV Stereo standard.

● All functions inclusive matrix adjustment are I²C bus controlled

● Inputs for AM sound or NICAM

● SCART interface

● Independent headphones

● Universal clock generation circuit build-in

● Clipping detector build-in

● Volume control

● High signal-to-noise ratio

● Extremely low total harmonic distortions

● High security for the detection of the identification signals because of the digital interference suppression and the very narrow bandwidth
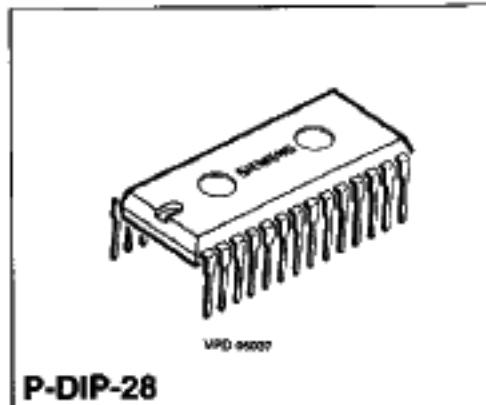

P-DIP-28

Type	Ordering Code	Package
TDA 6612	Q67000-A5034	P-DIP-28

The IC is divided into three functional blocks

1. Stereo Sound Processing with High Performance (exceeds DIN 45500; suitable for NICAM and CD)

a) Matrix for G-standard with crosstalk compensation controlled via the I²C bus

b) Additional single channel AF input (for e.g. AF signal according to L-standard)

c) Stereo SCART interface according to FTZ official specification

d) Stereo loudspeaker signal section with Ch1/Ch2 switch, bass/treble control, quasi stereo/stereo base width expansion and separate loudspeaker volume control for left and right (balance)

e) Separate stereo head phone signal section with Ch1/Ch2 switch and volume control

2. TV Sound Identification Signal Decoder Consisting of:

a) Active pilot signal filter

b) Phase independent rectifier with very narrow bandwidth for evaluation of the identification signal

c) Digital integrator to reduce interferences by noise

d) Multiplexer for cyclical switch over between "stereo" or "dual" evaluation

e) Reference signal generation with externally synchronized PLL

- synchronization with external H-sync pulse or 62.5-kHz clock
- build-in crystal oscillator and external 4-MHz crystal
- external 4-MHz (or 1-MHz) clock signal

Control Section for:

a) I²C bus interface with listen/talk function

b) Control of the complete AF sound signal detector

c) Read access to the clipping detector

d) Control of the identification signal decoder

e) Reading of the status of the identification signal decoder

f) Test modes

Circuit Description

Signal Section

The audio signal processing in the matrix and the switch-over for multi channel TV sound signals according to the two carrier system used in Germany takes place in the matrix and switching sections. Crosstalk compensation is carried out in the sound 1 input stage. The crosstalk compensation range has an adjustment range of ± 3 dB with a step width of 0.2 dB. In addition to the two inputs for the demodulated sound carrier a two channel SCART input and an additional mono input (e.g. for demodulated L-standard sound) are provided. The two AF (pin 1 and pin 2) inputs can be bypassed internally in such a way that decoded stereo sound of other audio systems (NICAM) can be processed. The switching section includes also the SCART output with the possibility to select the sound 1 or 2 during the "Dual" mode. The Ch1/Ch2 switches for the loudspeaker and headphone outputs are independently switchable.

In the signal path for the volume control unit output there is the Ch1/Ch2 switch followed by two different volume control units. The first has a control range from 0 to − 15 dB with a step width of 1.25 dB. In conjunction with the main volume control after bass and treble control a high immunity against overdriving the output stage is reached. The first volume control is used as a "pre-stage" of the main volume control in conjuntion with the clipping detector. This section is followed by a switchable quasi stereo stage which provides a stereophonic audio effect with mono signals due to a 180° phase shift at medium frequencies (about 1 kHz) in one channel. The following bass control has a control range of +15/−12 dB with a step width of 3 dB. The cutoff frequency for each channel is set with an external capacitor. The implemented switchable circuit for stereo base width expansion provides a three dimensional aural reception. This is realized with a 50% frequency dependent crosstalk with opposite phase of the signal between both channels. The circuit operates with the same cutoff frequency as the bass control, but the function is widely independent. The treble control has a step width of 3 dB with an control range of +/−12 dB. The cutoff frequency of the treble control is derived from one capacitor for each channel. The loudspeaker signal path is terminated with the loudspeaker control, independently adjustable for left and right. With 57 steps of 1.25 dB the adjustement range is 70 dB, where step 57 activates the "MUTE" function. Functions such as "balance" or "loudness" are realized by software and adjustment of the appropriate tone and volume controls. In the volume control unit there is a clipping detector. The status of the clipping detector can be evaluated via the I²C bus. Therefore it is possible to implement an automatic volume control using the clipping detector and software implemented into the controller.

After every evaluation the clipping bit is reset. Therefore after a read access to the clipping bit a new evaluation of the clipping detector status is possible.

The signal path for the headphones contains a volume control after the Ch1/Ch2 switch with a common adjustment for left and right. Thirty two steps of 2 dB give an adjustment range of 62 dB (31 x 2 dB = 62 dB, the 32nd step is MUTE).

Identification Signal Decoder

The input of the identification signal decoder consists of an op-amp for the pilot signal with its side bands. An external LC circuit is used. The signal is then passed to a phase independent active band-pass filter with a very narrow bandwidth (adjustable externally). This

filter detects whether the lower side band of the pilot carrier, which is modulated with the identification signal, is present. The center frequency of the filter is switched between "dual" and "stereo" by a multiplexer. The multiplexing frequency is adjustable by software. If a side band is detected, the multiplexer stops. The interferences on the first "detected" criterion are suppressed by a digital integrator with a following comparator and can be read out via I²C bus (talk mode) as the "stereo" or "dual" mode. The control of the corresponding signal can be either directly internally or through the µC. All the necessary clock signal are derived from a fast setting PLL which is synchronized by a reference frequency. This reference frequency must be sufficiently close to the horizontal frequency, but a **rigid phase coupling is not required**. Therefore, alternatively the use of a crystal controlled 62.5-kHz frequency commonly found in PLL tuning systems is possible. A further alternative for the clock signal generation is a build-in crystal oscillator with an external 4-MHz crystal or the use an external 1- or 4-MHz clock frequency.

Control Section

All functions are controlled via an I²C bus interface with "listen" / "talk" functions. The data bytes currently used are stored in a block of latches.

The telegram structure is formed in the following manner:

start condition - chip address - any number of bytes - stop condition

The following conditions apply to the data bytes:

Before the actual data byte (with the adjustment information), always an I²C bus sub-address byte has to be transmitted. The I²C bus interface however is interpreting this sub-address byte as a data byte.

Example: The headphone volume is to be increased in a number of steps.

Right	Wrong
Start condition	Start condition
Chip address 84 (Hex)	Chip address 84 (Hex)
Sub-addr. vol. HP 03 (Hex)	Sub-addr. vol. HP 03 (Hex)
Vol. step 8 08 (Hex)	Vol. step 8 08 (Hex)
Sub-addr. vol HP 03 (Hex)	Vol. step 9 09 (Hex)
Vol. step 9 09 (Hex)	Vol. step 10 0A (Hex)
Sub-addr. vol. HP 03 (Hex)	Stop condition
Vol. step 10 0A (Hex)	
Stop condition	

Within a telegram (i.e. without a new start condition) any different sub-addresses can be accessed. The changeover between "listen" and "talk" access to the IC however must always occur using the following sequence: stop condition - start condition - chip address. Before each read access always a start condition and chip address (talk) must be transmitted. The data to be read out are then loaded into the I²C bus interface and can be transferred to the µC.

Chip Address

MSB	•	•	•	•	•	•	LSB

SIEMENS AKTIENGESELLSCHAF

UEB03423

Left Right AF Loudspeaker — 0.47 µF 15, 0.47 µF 16

Volume Main Control

Base Width

Bass

Cut-Off Frequency Bass — 14 47nF, 13 47nF

Cut-Off Frequency Treble — 1.5nF 17, 1.5nF 18

Treble

Clipping Detector

Quasi-Stereo

Phase Rotation Quasi-Stereo — 12 6.8nF, 11 6.8nF

Volume Precontrol

Left Right AF Headphones — 0.47 µF 19, 0.7 µF 20

Volume Headphones

SCART Output Mono Mono Sound1 Sound 2 Left Right — 10 0.7 µF, 9 0.47nF

Reference Voltage

Switch

SCART Input Left Right Sound 1 Sound 2 — 8 100nF, 7 100nF

V_S 21 10µF

I²C Bus SCL 22, SDA 23

I²C Bus

AF Input I Standard — 6 100nF

4-MHz Quarz — 27pF 24

54-kHz Filter — 5 2.2nF, 4 3.9mH, 54-kHz Filter

Bandw. ID Signal Decoder — 1µF 25

Filter

Multiplexer

Loop Filter PLL — 680 pF, 56kΩ, 3.3nF 27, 28

PLL

Integrator

Matrix

Adjust.

12KΩ, 100nF 10nF, 5.6kΩ, 1nF — 3 AF Input Sound 2, Right

10µF 2 Bias AF Unit

100nF 1 5.6kΩ — AF Input Mono, Sound 1 (L + R)/2, Left

10nF

Application Circuit 3

SIEMENS

TDA 6612

I²C Bus Timing Diagram

t_{SUSTA}	Set-up time (start)
t_{HDSTA}	Hold time (start)
t_{HIGH}	High pulse width (clock)
t_{LOW}	Low pulse width (clock)
t_{SUDAT}	Set-up time (data transfer)
t_{HDDAT}	Hold time (data transfer)
t_{SUSTO}	Set-up time (stop)
t_{BUF}	Bus free time
t_F	Fall time
t_R	Rise time

All times are referenced to the V_{IH} and V_{IL} values.
